

Node.js Quick Summary

1. Modules in Node.js

module.exports shares code from one JavaScript file with another.

```
// math.js
const sum = (a, b) => a + b;
const multiply = (a, b) => a * b;

module.exports = { sum, multiply };
// script.js
const math = require("./math");

console.log(math.sum(5, 10));
```

2. ES Modules (ESM)

If package.json contains **"type": "module"**, .js files use ES Module syntax.

```
// math.js
export { sum, multiply };

// script.js
import { sum, multiply } from "./math.js";
```

CommonJS: module.exports + require()

ES Modules: export + import

3. process.argv

process.argv contains command-line arguments passed to a Node.js program.

```
node script.js Kush Canada

// index 0 = Node
// index 1 = script path
// index 2 = Kush
// index 3 = Canada
```

4. Git Bash: Moving Between Folders

pwd → shows the current directory

ls → lists files/folders

cd folder → enters a folder

If a folder name contains spaces, use quotes:

```
cd "New folder"
cd "Zerodha Clone"
cd backend
node script.js
```

5. Common Error

If Node says **Cannot find module 'C:\Users\lbhavn\script.js'**, you are probably running the command from the wrong directory. Use **pwd**, then **cd** into the folder containing script.js.

Remember: require() receives what another module exports. import receives what another ES module exports.
